# World Energy Outlook

# World Energy Outlook 2009

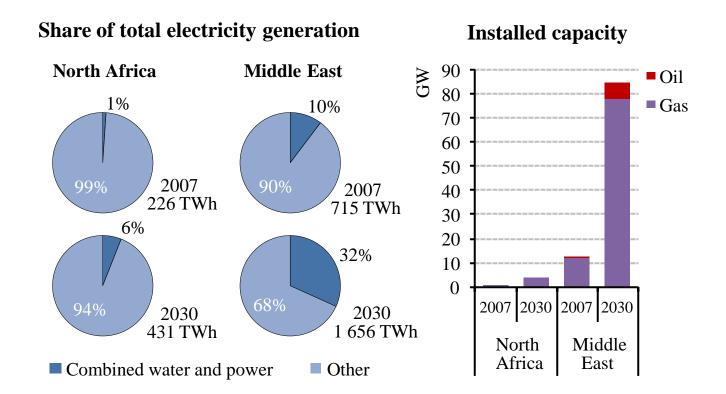

Dr. Fatih Birol IEA Chief Economist Riyadh, 12 January 2010

Change in primary energy demand in the Reference Scenario, 2007-2030

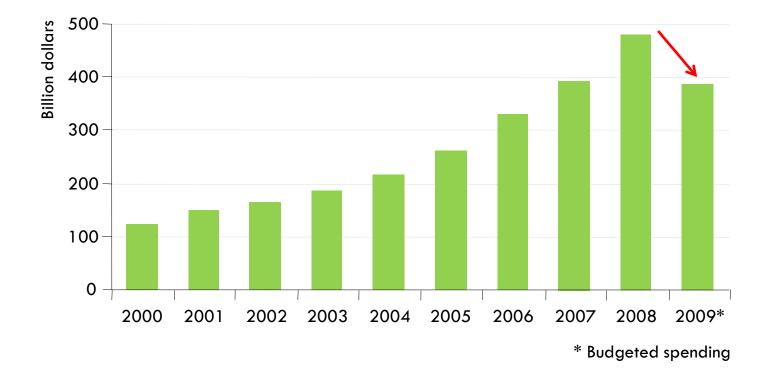

Fossil fuels account for 77% of the increase in world primary energy demand in 2007-2030, with oil demand rising from 85 mb/d in 2008 to 88 mb/d in 2015 & 105 mb/d in 2030

Electricity generation from combined water and power plants in Middle East and North Africa

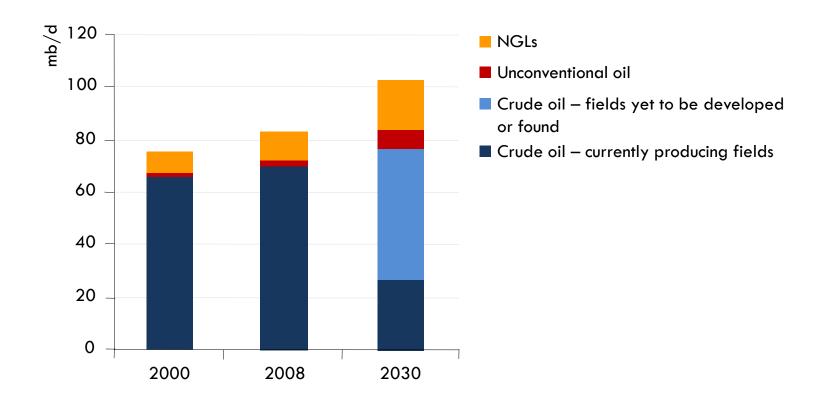

By 2030 almost one-third of electricity production and capacity additions in the Middle East will come from combined water and power plants.

## Worldwide upstream oil & gas capital expenditures

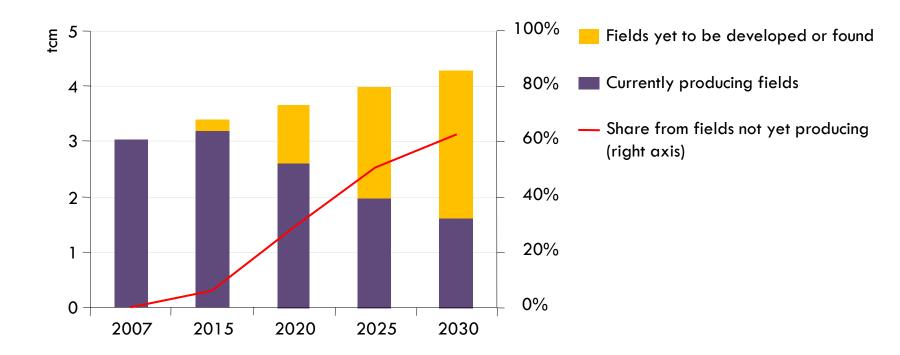

#### Global upstream spending (excluding acquisitions) is budgeted to fall by over \$90 billion, or 19%, in 2009 – the first fall in a decade

### Oil production in the Reference Scenario

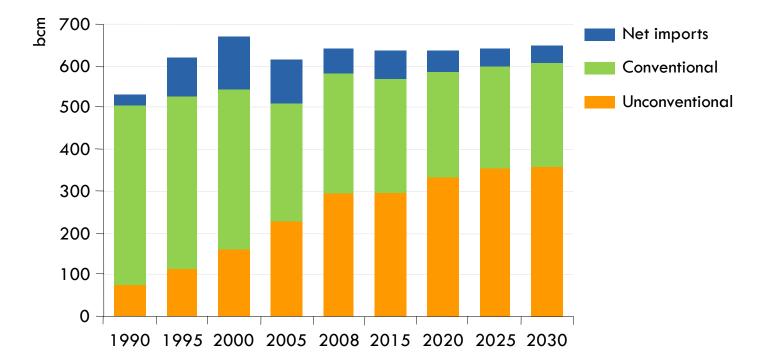

Sustained investment is needed mainly to combat the decline in output at existing fields, which will drop by almost two-thirds by 2030

### Impact of decline on world natural gas production in the Reference Scenario

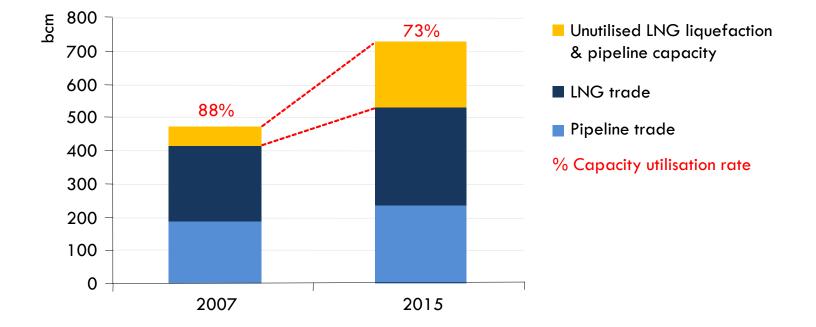

Additional capacity of around 2 700 bcm, or 4 times current Russian capacity, is needed by 2030 – half to offset decline at existing fields & half to meet the increase in demand

### US natural gas supply in the Reference Scenario

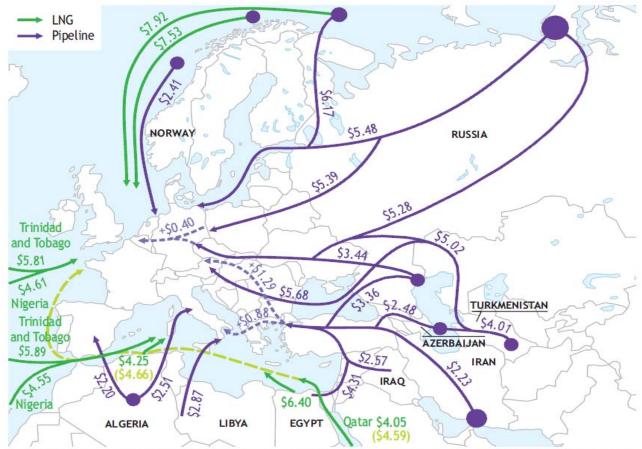

Mainly as a result of shale gas production growth, US gas output grows gradually through to 2030, outstripping US demand & squeezing US net imports

#### Natural gas transportation capacity

A glut of gas is developing – reaching 200 bcm by 2015 – due to weaker than expected demand & plentiful US unconventional supply, with far-reaching implications for gas pricing

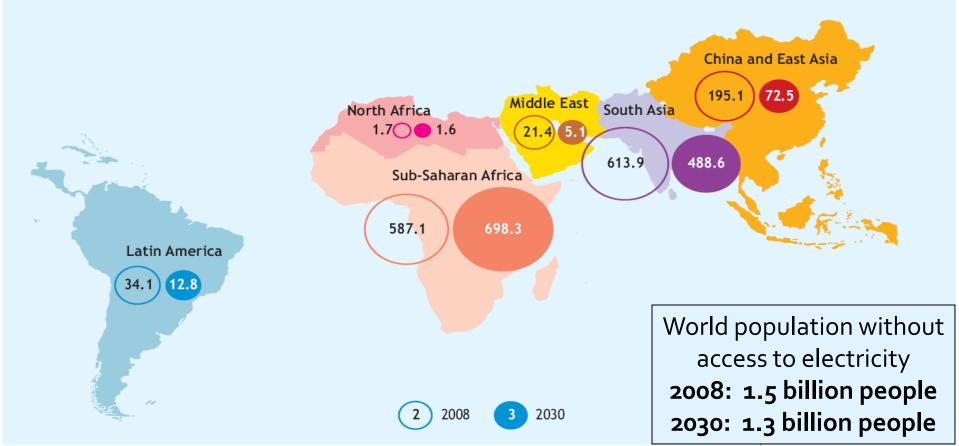

# Indicative costs for potential new sources of gas delivered to Europe, 2020 (\$/MBtu)

The boundaries and names shown and the designations used on maps included in this publication do not imply official endorsement or acceptance by the IEA.

Although indigenous resources are limited & output is declining, Europe is geographically well placed to secure gas supplies from a variety of external sources

### Number of people without access to electricity in the Reference Scenario (millions)

The boundaries and names shown and the designations used on maps included in this publication do not imply official endorsement or acceptance by the IEA.

\$35 billion per year more investment than in the Reference Scenario would be needed to 2030 – equivalent to just 5% of global power-sector investment – to ensure universal access

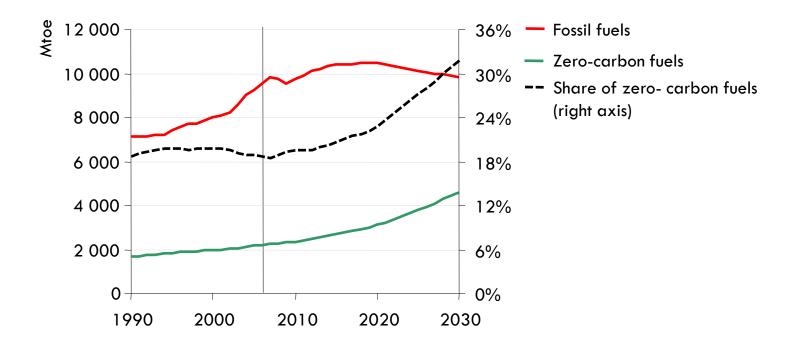

## The policy mechanisms in the 450 Scenario

- A combination of policy mechanisms, which best reflects nations' varied circumstances & negotiating positions
- We differentiate on the basis of three country groupings
  - > OECD+: OECD & other non-OECD EU countries
  - > Other Major Economies (OME): Brazil, China, Middle East, Russia & South Africa
  - > Other Countries (OC): all other countries, including India

#### A graduated approach

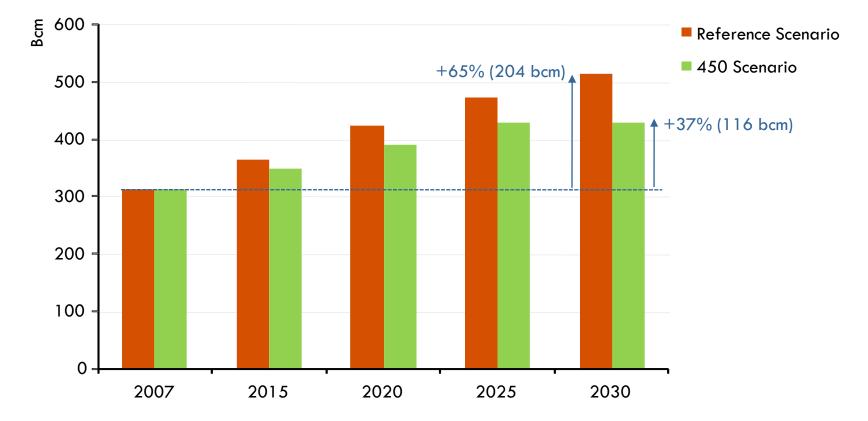

- > Up to 2020, only OECD+ have national emissions caps
- > After 2020, Other Major Economies are also assumed to adopt emissions caps
- > Through to 2030, Other Countries continue to focus on national measures
- Emissions peaking by 2020 will require
  - > A CO<sub>2</sub> price of \$50 per tonne for power generation & industry in OECD+
  - Investment needs in non-OECD countries of \$200 billion in 2020, supported by OECD+ through carbon markets & co-financing

# World primary energy demand by fuel in the 450 Scenario

In the 450 Scenario, demand for fossil fuels peaks by 2020, and by 2030 zero-carbon fuels make up a third of the world's primary sources of energy demand

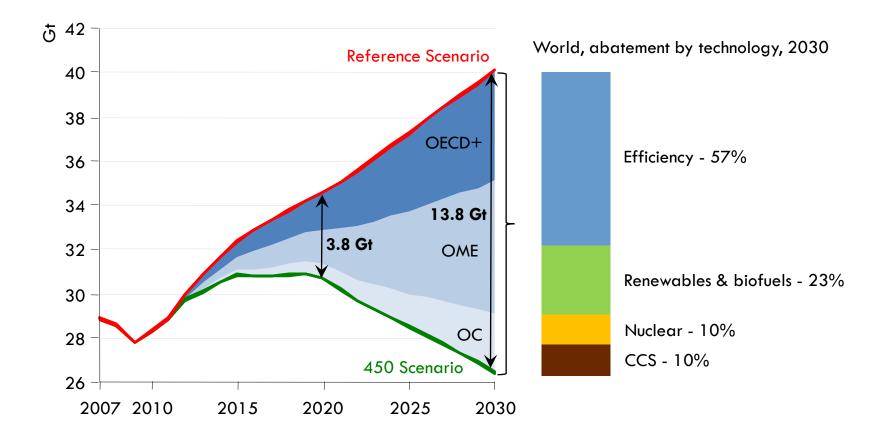

## EU primary natural gas imports by scenario

EU gas imports continue to grow in the 450 Scenario, but plateau by the mid-2020s... Chinese gas imports soar to 90 bcm in 2030.

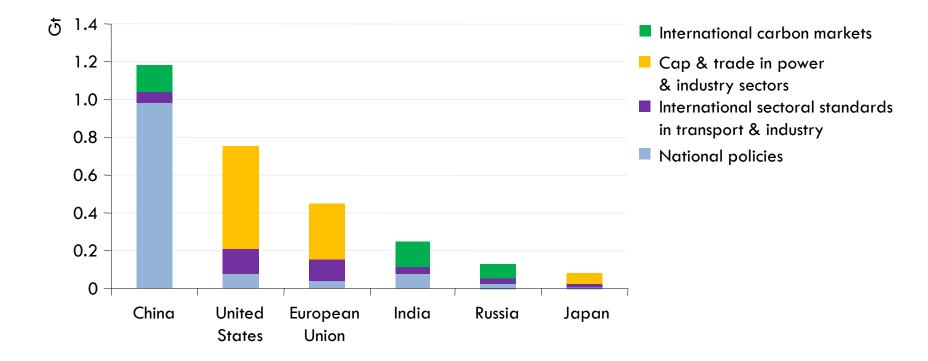

© OECD/IEA - 2009

## World abatement of energy-related CO<sub>2</sub> emissions in the 450 Scenario

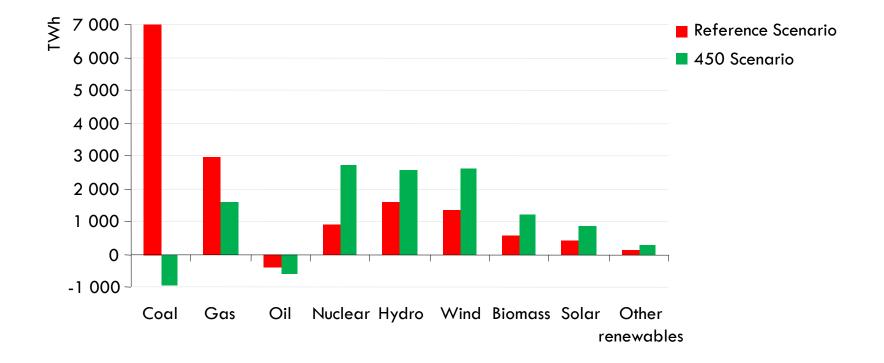

An additional \$10.5 trillion of investment is needed in total in the 450 Scenario, with measures to boost energy efficiency accounting for most of the abatement through to 2030

#### Abatement in the 450 Scenario by key emitters, 2020

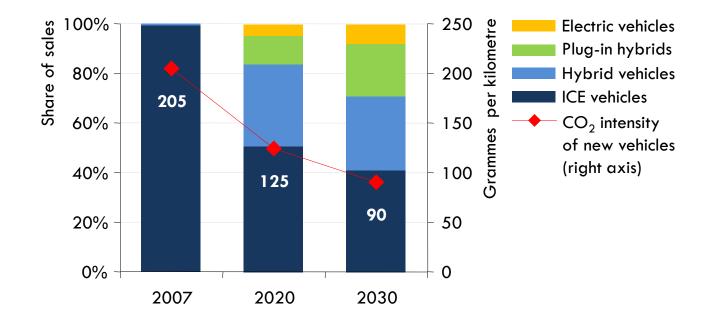

China, the United States, the European Union, India, Russia & Japan account for almost three-quarters of the 3.8 Gt reduction in the 450 Scenario

Incremental world electricity production in the Reference and 450 Scenarios, 2007-2030

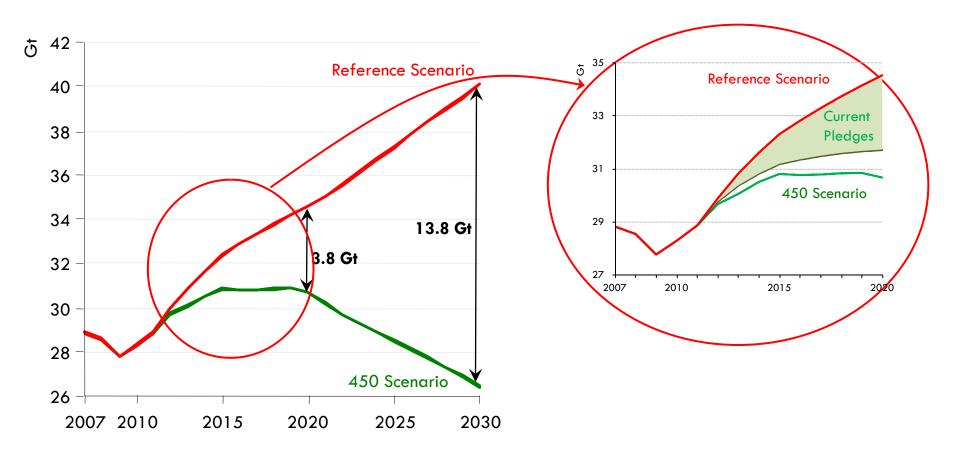

Renewables, nuclear and plants fitted with CCS account for around 60% of electricity generation globally in 2030 in the 450 Scenario, up from less than one-third today

World passenger vehicle sales & average new vehicle CO<sub>2</sub> intensity in the 450 Scenario

Improvements to the internal combustion engine & the uptake of next-generation vehicles & biofuels lead to a 56% reduction in new-car emission intensity by 2030

## World abatement of energy-related CO<sub>2</sub> emissions in the 450 Scenario

#### Current pledges point in the right direction but further efforts would be needed to reach the 450 Scenario

#### Summary & conclusions

- The financial crisis has halted the rise in global energy use, but its long-term upward path will resume soon on current policies
- Oil investment has fallen sharply, posing questions on medium term supply
- A sizable glut of natural gas is looming
- A 450 path requires massive investments but would bring substantial benefits
- Natural gas can play a key role as a bridge to a cleaner energy future
- The challenge is enormous but it can and must be met
